

CSE 11

Accelerated Intro to Programming

Lecture 5

Greg Miranda, Spring 2021

Announcements

- Quiz 5 due Friday @ 8am
- PA1 due tonight @ 11:59pm → PA1 resubmission
- Survey 2 due Friday @ 11:59pm

Discussion 4pm 5pm
↳ PA2

Argument

"banana"

"hello"

"a"

Result

"ban"

"he"

?

or "hel"

""

empty string

- String example program

```
class StringExamples {  
}
```

- Write a method called firstHalf that:

- Takes a String and returns a new String that has just the first half of the characters from the input String *(round down)*

- When writing a method:

- Think about what some examples are and what we expect the results to be:
 - We can write these down as fields
 - Then we can easily check if we are right after running the program
- Examples first – then build up into the implementation
 - Do on paper/whiteboard first – then type them in

→ unit test → test code to see if it works

- One of the first things to think about is:
 - What method (or methods) out of the methods we saw on strings is going to be useful here
 - We will be able to accomplish this only with methods we have seen so far

→ length

→ substring (int s, int e)

repeat

replace

indexOf

"banana" 6

↑

↑

- This showed us how to implement a method from a word problem prompt
- We thought through some examples
 - Which helped us to refine our understanding
- We experimented a little bit
 - Figured out we are okay with this empty String result
- This is the process we should use when implementing methods
 - i.e. Programming Assignments

New Data Type

- Previous data types:

→ String

→ int

- Examples

• boolean b1 = 4 < 5;

• boolean b2 = 5 < 4;

- New data type:

• Boolean → boolean

• Uses different kinds of operators

• Comparison operators

less than

true

false

- String – many different types of strings, infinite # of strings

- Only limited by how much memory is in our computer

- int – somewhat limited

2^{32}

- -2,147,483,648 to 2,147,483,647

- Boolean – only two values

- true / false

- Represents the answers to yes or no questions

- $4 < 5$

- Asking the question: is 4 less than 5?

yes

true

<u>String</u>	<u>int</u>	<u>boolean</u>
"a"	-2	true
"Apple"	-1	false
⋮	0	
	1	
	2	
	⋮	
arbitrary # of elements		just 2 values

- Many boolean operators

- `boolean b3 = 4 == 4;` *//checks for equality*

- `boolean b4 = 4 == 5;` ✓

- `=` is not the same as `==`

- `=` is used to create or initialize a field definition

- Assignment operator

- `boolean b5 = 5 > 4;`

- `boolean b6 = 5 >= 4;`

- As well as `<=`

- All of these are ways to compare numbers

- Gives true/false (yes or no) answers

- What happens if we use it to compare Strings?

- `boolean stringComp = "a" < "b";`

- Useful idea when learning a new feature
 - Ask if it works with other things you've worked with before
- Comparison operators like < and > do not type check
 - Only numeric types work with Java's type checking
- What about == on Strings?
 - `boolean stringComp = "a" == "a";`
 - `==` does produce an answer on Strings
 - `boolean stringComp = "a" == "b";`
 - Does produce an answer, but not recommended for Strings
 - We will talk more about comparing Strings for equality in future weeks
 - Only use `==` for numeric comparisons in this course

↑
int

- Main lesson:

- 2 new values

- true/false

- With new data type boolean

- New relational and comparison operators that work with booleans

- < >
 - <= >=

- ==

- Another comparison operator

- !=

- boolean b7 = 4 != 5;

- boolean b8 = 5 != 5;

- Opposite of the == answer

! → not

!= → not equals

Boolean Operations

- What can you do given a boolean?
 - What if we want to ask more than simple questions
 - Are two things true at the same time?
 - Is one of two things true?

- Combining booleans into another boolean

- boolean and1 = true && true;
- boolean and2 = true && false;
- boolean and3 = false && true;
- boolean and4 = false && false;

true && → and
both sides must
be true

- boolean or1 = true || true;
- boolean or2 = true || false;
- boolean or3 = false || true;
- boolean or4 = false || false;

true
true
true
false || → or
one side must
be true

Methods with Booleans

2 and up
 $N \geq 2$

- Number line 1

- Problem:

- Write a method that takes a number and returns true if it's in the region in our number line example

- Examples: *Argument*

Expected

unit tests [

2

true

5

true

-1

false

```
boolean numberLine2(int number) {  
    return (number > 5) && (number < 7) || (number < 2);  
}
```

- What does this number line look like?

2 5 before 11

More Complicated Questions with Methods

- Write the method to calculate absolute value that takes a number and returns the negation if it's less than 0, or that number otherwise
- Examples:
 - `int abs1 = this.absolute(-2);` `//should produce 2`
 - `int abs2 = this.absolute(4);` `//should produce 4`

```
int absolute(int number) {  
}
```

- Important comparison we need to do here
 - Is the number less than 0?
 - number < 0
 - Don't want to return true or false, we want to return the right number
- New Java syntax:
 - if statement

stop

if (cond) {

→

[else if (cond) {

}

else {

}

Weekly Pay Problem

- `weeklyPay`: takes a number of hours worked and an hourly rate, and returns the pay with overtime (over 40 hours) counting as double the rate
- Examples:
